

# Instructions

This manual provides instructions on the installation and execution of the software and a brief explanation of various input parameters and outputs of the software ‘PrEP Predictor’ [1]. The mathematical and technical details can be found in the main manuscript and Supplementary Notes of [1].

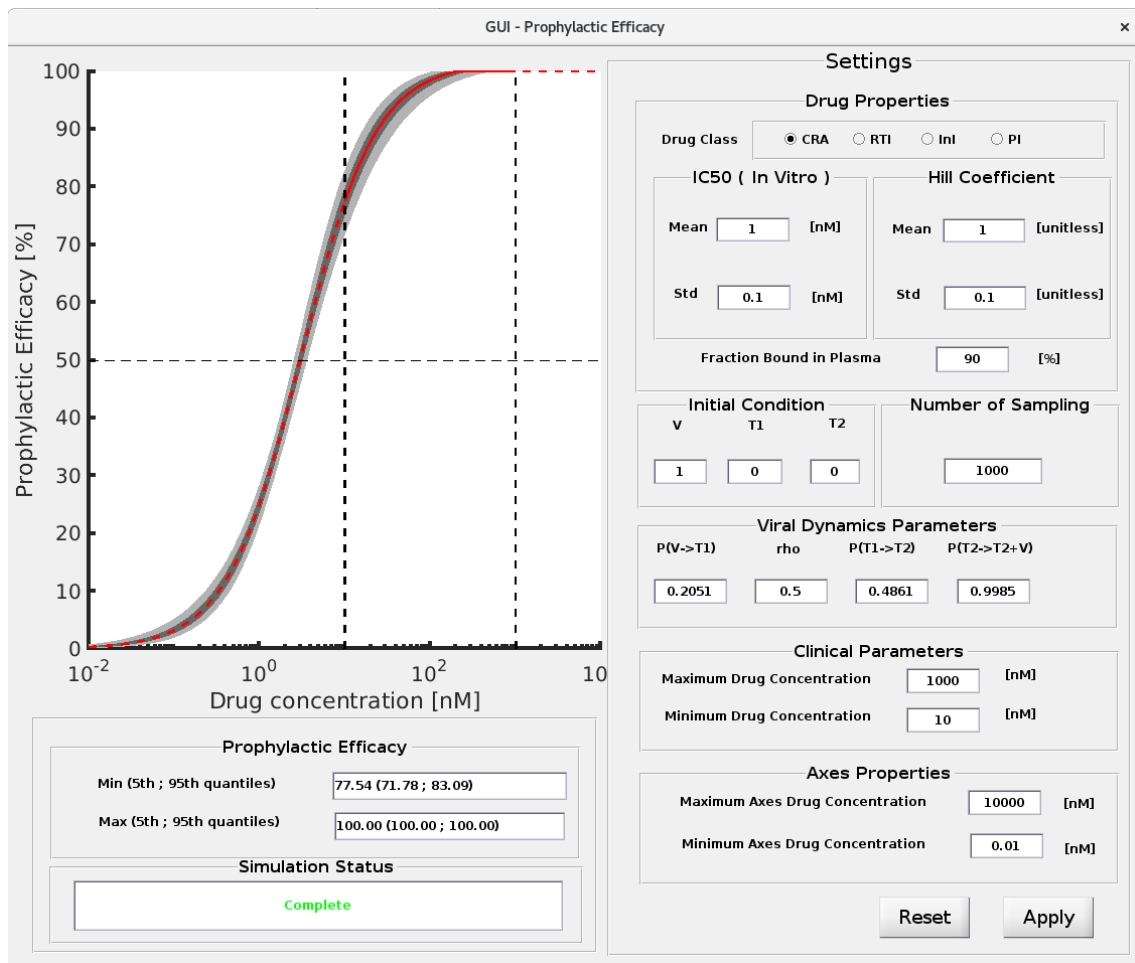

Figure 1: Graphical user interface of ‘PrEP Predictor’

## Installation and execution of the software

- For the windows OS, we provide an installer which upon the execution will download the *Matlab Compiler Runtime*. The *Matlab Compiler Runtime* allows a user to run the software without Matlab. The software is installed in the local computer and can be found with window starter programs.
- For the linux OS, the user needs to manually download *Matlab Compiler Runtime R2018a (MCR)*. The link to MCR is :  
<https://de.mathworks.com/products/compiler/matlab-runtime.html>  
The further details of executing the software can be found in ‘readme.txt’.

## Inputs

### Drug Properties.

The screenshot shows a form titled "Drug Properties". At the top, there is a "Drug Class" section with four radio buttons: CRA (selected), RTI, InI, and PI. Below this, there are two main sections: "IC50 ( In Vitro )" and "Hill Coefficient". The "IC50" section has two input fields: "Mean" with the value "1" and unit "[nM]", and "Std" with the value "0.1" and unit "[nM]". The "Hill Coefficient" section has two input fields: "Mean" with the value "1" and unit "[unitless]", and "Std" with the value "0.1" and unit "[unitless]". At the bottom of the form, there is a "Fraction Bound in Plasma" section with an input field containing "90" and the unit "[%]".

Figure 2: Properties related to the drug of interest.

A user can select a drug class from a list of four drug classes, namely co-receptor antagonist (CRA), reverse transcriptase inhibitor (RTI), integrase inhibitor (InI) or protease inhibitor (PI). Drug specific parameters such as the 50 % inhibitory concentration  $IC_{50}$  and a hill coefficient from single-round infectivity assays can be typed into the corresponding fields. The  $IC_{50}$  is assumed to be log normal distributed, whereas the hill coefficient is assumed to be normal distributed. The user also needs to provide the fraction of drug bound to plasma proteins in percentage.

### Viral Exposure.

The screenshot shows a form titled "Initial Condition". It has three input fields labeled "V", "T1", and "T2". The values entered in these fields are "1", "0", and "0" respectively.

Figure 3: Initial condition relating to the viral exposure.

The prophylactic efficacy of the administered drug class depends on the intensity of viral exposure, herein defined by the number of free infectious viruses  $V$ , early infected T-cells  $T_1$  and productively infected T-cells  $T_2$  within a replication-competent compartment. Note that we do not refer to e.g. the mucosal exposure, but rather the number of viral species passing the mucosal barrier and reaching a compartment rich in target cells ( $CD4^+$  immune cells). This allows the user to explore prophylactic efficacy depending on the intensity of virus exposure.

### Viral dynamics parameters.

The user can specify various viral dynamics parameters. The values of these parameters correspond to a drug-free condition. The term  $(P(V \rightarrow T_1))$  denotes the probability that a virus infects a T-cell and advances to early infected T-cell  $T_1$  (after completion of reverse transcription, but before proviral integration). The term  $\rho$  denotes the probability to successfully complete reverse transcription. Similarly the term  $(P(T_1 \rightarrow T_2))$  and term  $(P(T_2 \rightarrow T_2 + V))$  denote the probability that a  $T_1$  advances to a productively infected T-cell  $T_2$  (after proviral integration) and

Viral Dynamics Parameters			
P(V->T1)	rho	P(T1->T2)	P(T2->T2+V)
0.2051	0.5	0.4861	0.9985

Figure 4: Viral dynamics parameters.

that a  $T_2$  cell produces a free virus. Further details of these parameters can be found in Supplementary Text S1 of [1].

### Number of samplings.

Number of Sampling
1000

Figure 5: Number of random samplings performed for the computation of prophylactic efficacy.

The number of sampling denotes the number of realizations where an  $IC_{50}$  and a hill coefficient are randomly sampled from the user-defined distribution.

### Clinically achievable drug concentration in plasma.

Clinical Parameters		
Maximum Drug Concentration	1000	[nM]
Minimum Drug Concentration	10	[nM]

Figure 6: Clinically relevant drug concentration range in blood plasma.

The range of clinically achievable drug concentration in plasma can be specified, which allows to consider variability due to dosing regimen and pharmacokinetics. The unit is nanomolar [nM].

### Axes concentration range.

Axes Properties		
Maximum Axes Drug Concentration	10000	[nM]
Minimum Axes Drug Concentration	0.01	[nM]

Figure 7: Drug concentration to adjust x-axis of the concentration-prophylaxis profile plot.

This allows the user to adjust the x-axis i.e. concentration range to be displayed in the plot.

## Buttons.

Figure 8: Buttons.

Pressing the button 'Apply' will perform the computation based on the user defined inputs. The button 'Reset' resets inputs variables to initially pre-defined values.

## Outputs

### Concentration-prophylaxis plot.

Figure 9: Concentration-prophylaxis plot.

Based on the user defined inputs, the display shows the concentration-prophylaxis profile for the drug (relative reduction in infection probability). The dashed colored line represents the median prophylactic efficacy and is plotted in one of the four colors depending on the selected drug class. The green color represents RTI, whereas red, blue and purple represent CRA, InI and PI respectively. The solid colored line denotes concentration-prophylaxis profile within the clinically achievable concentration ranges. Light and dark grey areas indicate 25<sup>th</sup>-75<sup>th</sup> and 5<sup>th</sup>-95<sup>th</sup> percentiles respectively. The horizontal dashed line marks 50% prophylactic efficacy. The two vertical dashed lines represent the drug concentration range (minimum – maximum concentrations provided by the user).

## Prophylactic efficacy within concentration range.

Prophylactic Efficacy	
Min (5th ; 95th quantiles)	77.60 (71.94 ; 83.39)
Max (5th ; 95th quantiles)	100.00 (100.00 ; 100.00)

Figure 10: Concentration-prophylactic efficacy within concentration range.

The text box shows the minimum and maximum prophylactic efficacy achieved along with their respective 5<sup>th</sup>-95<sup>th</sup> percentiles.

## Simulation status display.

Figure 11: Text showing simulation status: The leftmost panel shows the displayed text when the simulation completed without problem. The rightmost panel shows an instance where the simulation encountered a problem.

The text box shows the end status of simulation. If the simulation executed without problem, a text in green reading 'complete' is shown. If the simulation encounters problem, a text in red is showing instructions to solve the error.
